alirs232upgradetoolv120downloader15 examples one of the main problems with electric vehicles is the limited range. as the battery capacity or lithium-ion capacity is limited the total range would be even more limited. but an important step in developing new battery technologies could be taken. using a new mathematical model, researchers from the eth zürich and the karlsruhe institute of technology (kit) have been able to derive predictions on the power and energy density of future li-ion batteries. the model can be used to identify the ideal battery chemistry for a specific application and to predict battery technology development and its limits. the researchers used a battery electrode based on lithium iron phosphate (lfp), a lithium and iron alloy that has particularly good cycle stability. similar to graphite, lfp offers a highly conductive and flexible structure. and the high polarization energy at lfp electrodes allows the safe operation of li-ion batteries in harsh environments. battery technology will change as a result of advances in cell design and application. the possible development of electric vehicles with a range of several hundred kilometers is expected, while battery technology developments in the area of stationary applications on the other hand, are currently aimed at ensuring the supply of energy in the most

effective and reliable way. the researchers focused on the calculation of battery charge power and energy density for their new mathematical model. the model is based on electrochemical, physical and chemical analysis. the motivation for creating the model was the potential application in the analysis of lithium-ion battery technology development. "for example, with the correct choice of battery materials, cycle stability can be significantly improved," says oliver hajj, scientist at the eth. current battery technologies offer the highest potential in stationary applications, with energy density of more than 500 watt-hours of energy per kilogram. as lithium-ion battery technology progresses the energy density of lithium-ion batteries will increasingly approach the energy density of current stationary energy sources such as diesel or natural gas. "the model can be used to select the best battery chemistry for a specific application with the hope of achieving the highest energy density," says saima siddiqui, a scientist at the eth and lead author of the study. future technology is expected to reach approximately 1,000 watt-hours per kilogram. the modeling has also identified the relevant parameters of future battery technology that are relevant for technology development, such as safety and cycle life. explore further rechargeable lithium-ion batteries perfect for electric vehicles more information: saima siddiqui et al. charge power and energy density predictions for lithium-ion batteries – state of the art and future directions, proceedings of the electrochemical society, american chemical society (acs), article no. 13, vol. 20, issue 14, pages 4367-4378, june 2018. saima siddiqui et al. doi: 10.1021/acs.chemmater.8b01437rejuvenation of the mental foramen using a lateral window approach: a technical note.
